

Bring's curve  $C$ : four handles,  $g = 4$

one function on  $C$ : carries  $2g + t_k = 12$  numbers

$2g = 8$  secret slots (one per handle, twice)

$t_k = 4$  pad

evaluate at 13 points on  $C$

13 helper-cards distributed to 13 player-parties

- $\leq t_k = 4$  cards: the 8 secret numbers stay uniform.
- $\geq t_T = 12$  cards: the function is determined; the 8 numbers fall out.
- Gap  $t_T - t_k = 2g = 8$ , twice the genus.
